

# Further Existence Results of Decompositions of Permutation Polynomial

Samuele Andreoli,  
George Petrides

# 1 Preliminaries

# 2 Our Contribution

# 3 Conclusions

# 4 References

# Why decompositions?

Permutation polynomials (PP) are at the base of many cryptographic primitives

- the inverse power function, notably, used for instance in AES
- generally, to achieve good cryptographic properties, have high degree

Much effort has gone into breaking down high degree PP into lower degree ones

- Reduce the area necessary for hardware implementations
- Enable area/latency tradeoffs
- Facilitate the usage of side-channel countermeasures, like masking or TIs

# Preliminaries

A function  $F : \mathbb{F}_p^n \rightarrow \mathbb{F}_p^n$  is called an  $(n, n)$ -function.

A  $(n, n)$ -function admits a representation as a univariate polynomial over  $\mathbb{F}_{p^n}$ , called *univariate representation*,

$$F(x) = \sum_{i=0}^{p^n-1} \alpha_i x^i.$$

The *algebraic degree* of  $F$  is  $d^\circ(F) = \max_{\alpha_i \neq 0} w_p(i)$ , where  $w_p$  is the  $p$ -weight.

A *power function* is a monomial  $x^k$ ,  $1 \leq k < p^n - 1$  and  $d^\circ(F) = w_p(k)$ .  
An invertible power function is a *power permutation*.

# Preliminaries

An invertible power function is a *power permutation*.

# Decomposition

A *decomposition* of a  $(n, n)$ -function  $F$  is a sequence of  $(n, n)$ -functions such that

$$F = G_1 \circ \dots \circ G_\ell.$$

For applications in hardware implementations, especially masked implementations, goals are

- algebraic degree of  $G_i$  should be small (typically 2 or 3),
- $\ell$  should also be as small as possible.

## Decomposition

A *decomposition* of a  $(n, n)$ -function  $F$  is a sequence of  $(n, n)$ -functions such that

$$F = G_1 \circ \dots \circ G_\ell.$$

For applications in hardware implementations, especially masked implementations, goals are

- algebraic degree of  $G_i$  should be small (typically 2 or 3),
- $\ell$  should also be as small as possible.

## Carlitz Theorem [Car53]

Let  $\mathbb{F}_q$  be a finite field, then all permutation polynomials are generated by  $x^{-1} = x^{q-2}$  and the affine polynomials  $ax + b$ , with  $a, b \in \mathbb{F}_q$ ,  $a \neq 0$ .

Which means, for any  $F(x)$  permutation polynomial in  $\mathbb{F}_{p^n}[x]$ ,

$$F(x) = A_1(x) \circ x^{-1} \circ A_2(x) \circ x^{-1} \circ \dots \circ A_{\ell-1}(x) \circ x^{-1} \circ A_\ell(x),$$

and  $A_i(x) = a_i x + b_i$ .

Further need to decompose  $x^{-1}$  into low algebraic degree functions  $G_j$ .

- use generic low degree polynomials,
- use low degree **power permutations**

## Carlitz Theorem [Car53]

Let  $\mathbb{F}_q$  be a finite field, then all permutation polynomials are generated by  $x^{-1} = x^{q-2}$  and the affine polynomials  $ax + b$ , with  $a, b \in \mathbb{F}_q$ ,  $a \neq 0$ .

Which means, for any  $F(x)$  permutation polynomial in  $\mathbb{F}_{p^n}[x]$ ,

$$F(x) = A_1(x) \circ x^{-1} \circ A_2(x) \circ x^{-1} \circ \dots \circ A_{\ell-1}(x) \circ x^{-1} \circ A_\ell(x),$$

and  $A_i(x) = a_i x + b_i$ .

Further need to decompose  $x^{-1}$  into low algebraic degree functions  $G_j$ .

Find decomposition

$$x^d = x^{e_1} \circ \dots \circ x^{e_\ell},$$

where all power functions have algebraic degree no greater than two (or three).

The problem is equivalent to finding

$$d = e_1 \dots e_\ell \pmod{p^n - 1},$$

where all factors have  $p$ -weight no greater than two (or three).

Find decomposition

$$x^d = x^{e_1} \circ \dots \circ x^{e_\ell},$$

where all power functions have algebraic degree no greater than two (or three).

The problem is equivalent to finding

$$d = e_1 \dots e_\ell \pmod{p^n - 1},$$

where all factors have  $p$ -weight no greater than two (or three).

# Previous Work

Search algorithm for  $p = 2$  in [NNR19]

- Compute all exponents  $b$  of 2-weight 2 in  $Z_{p^n}^*$ .
- Compute their orders  $m_b$ .
- Try all combinations of  $\prod_i b_i^{e_i}$  for  $e_i = 0, \dots, m_{b_i}$ .

Later improved by Petrides in [Pet23].

Decompositions for the inverse for infinite values of odd  $n$

- using only quadratic power permutations [Pet23]
- using quadratic and cubic power permutations [LSaa23].
- using one quadratic power permutation [APB<sup>+</sup>23]

# A criterion for the decomposition of the inverse

## Lemma

Let  $n$  be an integer and  $x^d$  a power permutation of  $\mathbb{F}_{2^n}$ . The inversion power permutation in  $\mathbb{F}_{2^n}$  admits a decomposition into the power function  $x^d$  if and only if  $\text{ord}(d)$  is even and  $\gcd(2^n - 1, d^{\frac{\text{ord}(d)}{2}} - 1) = 1$ .

If  $\text{ord}(d)$  is even, then

$$d^{\text{ord}(d)} - 1 \equiv \left(d^{\frac{\text{ord}(d)}{2}} - 1\right) \left(d^{\frac{\text{ord}(d)}{2}} + 1\right) \equiv 0 \pmod{2^n - 1}.$$

# A criterion for the decomposition of the inverse

## Lemma

Let  $n$  be an integer and  $x^d$  a power permutation of  $\mathbb{F}_{2^n}$ . The inversion power permutation in  $\mathbb{F}_{2^n}$  admits a decomposition into the power function  $x^d$  if and only if  $\text{ord}(d)$  is even and  $\gcd(2^n - 1, d^{\frac{\text{ord}(d)}{2}} - 1) = 1$ .

If  $\text{ord}(d)$  is even, then

$$d^{\text{ord}(d)} - 1 \equiv \left(d^{\frac{\text{ord}(d)}{2}} - 1\right) \left(d^{\frac{\text{ord}(d)}{2}} + 1\right) \equiv 0 \pmod{2^n - 1}.$$

# Speeding up the search

- Efficient to check if the order is even computing the Jacobi Symbol
- Computing  $\text{ord}(d)/2$  and checking directly is more efficient than computing the gcd

Next step, try to reduce the search space with some equivalence relation.

## Proposition

Let  $n \geq 3$  and  $d$  be integers such that the conditions of the Lemma are satisfied. The conditions are also satisfied for  $n$  and  $d' = 2^i d$  if and only if  $v_2(n) \leq v_2(i)$ .

- Only need to test  $d' = 2^i d$  for  $i = 0, \dots, v_2(n)$  for each  $d$ .

# Speeding up the search

- Only need to test  $d' = 2^i d$  for  $i = 0, \dots, v_2(n)$  for each  $d$ .

Further improvement is possible for quadratic  $d$ .

**Theorem. (A., Piccione, Budaghyan, Stănică, Nikova, 2023)**

Let  $n \geq 3$ . All permutations over  $\mathbb{F}_{2^n}$  admit a decomposition using quadratic and affine permutations if and only if  $4 \nmid n$ .

Test one representative  $d$  from each cyclotomic class, and  $2d$  if  $n$  is even.

More efficient computational search than previously known, with caveats:

- Might return a longer than optimal decomposition
- It does not return for all possible  $n$

We can further tweak the algorithm to achieve shorter decompositions.

**Example.  $n = 17, d = 3$**

$3^{422} \equiv 2^8 \cdot 9 \pmod{2^{17} - 1}$ , then  $-1 \equiv 3^{405} \equiv 2^8 \cdot 3 \cdot 9^{17} \pmod{2^{17} - 1}$ .  
Repeat with  $9^{17}$  to obtain the shortest decomposition.

Further improvement is possible for quadratic  $d$ .

**Theorem. (A., Piccione, Budaghyan, Stănică, Nikova, 2023)**

# Computational results

We run an exhaustive search for  $n$  up to 125 and we find many  $n$  for which the Lemma is satisfied.

3, 5, 6, 7, 10, 13, 14, 15, 17, 19, 23, 26, 30, 31, 34, 38, 43, 46, ...

Crucially, we might find families of **even** values of  $n$ .

The case of cubics: satisfied for all values up to 100, except

16, 32, 40, 48, 56, 60, 63, 64, 72, 75, 81, 84, 88, 96, ...

- Optimal length achieved for some (sparse) values of  $n$ .
- Improvement of some order of magnitude for most decompositions found in [LSaa23].

# The case of quadratics

## Conjecture

The conditions of the Lemma are satisfied by some quadratic  $d$  for an odd integer  $n$  if and only if they are also satisfied for  $2n$ .

- Computationally verified for  $n \geq 125$ .

## Why only a conjecture?

- Hard to prove the condition on the gcd if  $2^n - 1$  has many factors.
- No single  $d$  can be used for all even  $n$ .

# The case of quadratics

## Conjecture

- Computationally verified for  $n \geq 125$ .

## Why only a conjecture?

- Hard to prove the condition on the gcd if  $2^n - 1$  has many factors.
- No single  $d$  can be used for all even  $n$ .

## Theorem

Let  $p$  be a prime such that  $2^p - 1$  is also prime (a Mersenne prime). Then, the inversion power permutation in both  $\mathbb{F}_{2^p}$  and  $\mathbb{F}_{2^{2p}}$  has a decomposition into quadratic power permutations.

Proof by finding a suitable  $d = 2^{p-1} + 1$  and proving it satisfies the conditions of the Lemma.

- Trivial for  $n = p$ .
- For  $n = 2p$ , the key is that  $d^{-1} \equiv 2 \pmod{2^n - 1}$ , so we can rewrite

$$\gcd\left(2^p + 1, d^{\frac{\text{ord}_{2^{2p}-1}(d)}{2}} - 1\right) = \gcd\left(2^p + 1, 2^{\frac{\text{ord}_{2^{2p}-1}(d)}{2}} - 1\right)$$

# Work in progress

- Proving the conjecture for quadratics and using it to find other families.

## The case of cubics

- The conjecture might also hold for cubics
- Harder to find patterns when most values of  $n$  have suitable  $d$
- Finding families of  $d$  and  $n$  might be the right direction.

## Tweak the algorithm to obtain shorter decompositions

- Is the greedy approach sufficient to produce short decompositions?
- Is there an approach to guarantee optimal decompositions?
- Can we theoretically prove the existence of such congruences?

# Conclusions

- Criterion easy(ish) to use in proofs to find families
- First family of decompositions of the inverse for even values of  $n$ .
- With a small tweak, also efficient for computational searches
- Produce shorter decompositions than the state of the art

Thank you!
